ABSTRACT

Hazardous waste produced by industrial, medical, and chemical operations significantly jeopardises environmental sustainability, especially concerning soil and water resources. Poorly managed hazardous waste, such storing it wrong, throwing it away without care, or not treating it properly, is a big cause of soil and water pollution. The current study investigates the effects of hazardous waste management procedures on soil and water pollution, particularly in industrial areas. The project seeks to examine the impact of various phases of hazardous waste management – generation, collection, transportation, treatment, and disposal – on the quality of soil and both surface and groundwater resources. The study employs a descriptive and analytical research design utilising both primary and secondary data. Primary data were gathered via field observations and structured questionnaires distributed to industrial workers and environmental officials, whilst secondary data were sourced from government reports, environmental agencies, and published research publications. We looked at soil and water samples from some industrial locations to see how polluted they were, looking for things like heavy metals and chemical contaminants. We employed common environmental indicators like pH, total dissolved solids (TDS), chemical oxygen demand (COD), and heavy metal concentration to measure contamination levels.The results show that bad management of hazardous waste is strongly linked to higher levels of pollution in soil and water. Improper disposal and leaks from waste storage facilities were found to be important causes of pollution, which harmed the quality of the soil and the water supply. The study shows that firms that follow rules and use scientific ways to handle waste have less pollution. The study stresses the importance of stringent enforcement of environmental laws, the use of environmentally friendly waste management technology, and regular monitoring to lower environmental risks. The study enhances environmental management literature by offering pragmatic insights for the advancement of hazardous waste management methods to safeguard soil and water resources.

KEY WORDS: *Environmental Protection, Sustainable Waste Management, Industrial Waste, Soil Pollution, Water Pollution, and Hazardous Waste Management*

1. INTRODUCTION

The globe is creating a lot more hazardous garbage because of rapid industrialisation, urban growth, and new technologies. Hazardous waste is made up of things that are poisonous, corrosive, combustible, reactive, or infectious, and if not handled correctly, they can be very bad for people and the environment. Chemicals, pharmaceuticals, textiles, metals, petroleum, and healthcare are some of the biggest sources of hazardous waste. Improperly handling, storing, treating, and getting rid of this kind of garbage has become a major environmental problem, especially in developing countries.

Poor management of hazardous waste has a big impact on the ecosystem, especially on soil and water. When hazardous trash is thrown away in open landfills, dumped unlawfully, or kept without sufficient containment, poisonous chemicals can seep into the ground and pollute surface and groundwater. This pollution not only makes the environment worse, but it also hurts agriculture, drinking water safety, and the health of ecosystems. People who live near industrial regions are more at risk for the bad consequences of hazardous waste on land and water.

To reduce pollution in the environment, it is very important to follow good hazardous waste management procedures such separating, storing safely, treating scientifically, recycling, and disposing of safely. Governments have put in place standards for waste management and the environment to stop pollution from dangerous trash, but there are still big problems with how these rules are put into place and enforced. In this context, the current study investigates the effects of hazardous waste management techniques on soil and water pollution, underscoring the environmental repercussions of inadequate waste management and the necessity for sustainable and regulated waste management systems.

1.1 Background of Hazardous Waste Management

The idea of hazardous waste management came about because people were worried about the effects of industrial and chemical waste on the environment and public health. In the past, people routinely threw away industrial trash without thinking about how it would affect the environment in the long run. As industries grew, they started to produce more toxic waste, which polluted the land, water, and air, causing major health and environmental problems. This led governments and

international groups to see hazardous waste as a major environmental problem.

Hazardous waste management is the organised handling of garbage from the time it is made until it is thrown away in order to reduce its harmful impact on people and the environment. It involves things like finding, separating, collecting, storing, moving, treating, recycling, and safely getting rid of waste. Over time, managing hazardous waste has changed from basic ways to get rid of it to more complicated systems that focus on reducing waste, recovering resources, and protecting the environment.

After the Environment (Protection) Act, 1986, and the Hazardous and Other Wastes (Management and Transboundary Movement) Rules, hazardous waste management became more important in India. The goal of these rules is to make sure that hazardous waste is handled in a way that is good for the environment. Even if there are rules in place, problems including poor infrastructure, poor monitoring, industries not following the rules, and a lack of awareness nevertheless make it hard to carry out the rules effectively. To figure out how hazardous waste management helps keep land and water clean, you need to know where it came from.

1.2 What Hazardous Waste Is and What Kinds There Are

Hazardous waste is waste that has properties that can hurt people or the environment. This kind of trash could be poisonous, combustible, corrosive, reactive, or contagious. The chemical makeup, concentration, and physical properties of trash determine how dangerous it is. To keep the environment clean, these wastes need to be handled and thrown away in a certain way.

There are many different kinds of hazardous waste, including:
Industrial Hazardous Waste: This type of waste comes from making things like chemicals, paints, insecticides, oil refining, and metal processing.
comes from hospitals, labs, and other healthcare institutions. It includes infectious materials, sharps, and pharmaceutical trash.

Biomedical hazardous waste Chemical waste is made up of acids, alkalis, heavy metals, and other harmful substances.
E-waste is made up of dangerous chemicals including lead, mercury, and cadmium that come from old electronic devices.

Radioactive waste comes from nuclear power plants, research organisations, and medical uses.
Each kind of hazardous waste has its own dangers, and to keep land and water from getting polluted, it needs to be handled in the right way.

1.3 What Soil and Water Pollution Means and Why It Matters

Soil pollution is when dangerous things including chemicals, heavy metals, pesticides, and industrial waste get into the soil. This makes the soil less useful and lowers its quality. Contaminated soil has an impact on food safety, agricultural production, and the balance of ecosystems. Toxic chemicals can stay in the soil for a long time, which can hurt the ecology in the long run.
Water pollution happens when dangerous chemicals get into surface water bodies or groundwater. This makes the water unfit for drinking, irrigation, and aquatic life. Industrial waste, leaching from hazardous waste dumps, and throwing away trash in the wrong way are all major causes of water contamination. Water that is dirty can make you very sick, especially with waterborne diseases and long-term illnesses.

Soil and water pollution are important because they directly affect human survival, farming, biodiversity, and economic growth. For long-term growth and safety for the environment, it is important to protect soil and water resources.

1.4 Connection between Managing Hazardous Waste and Pollution of the Environment

The way hazardous waste is handled is intimately related to contamination in the environment, especially in water and soil. Toxic compounds can get into the soil and groundwater when hazardous waste is not properly managed, such as when it is dumped in open areas, put in unlined landfills, or released without oversight. Heavy metals, organic pollutants, and dangerous compounds are typically found in leachate from hazardous waste disposal sites. These substances can pollute nearby land and water bodies.

Bad storage and transportation methods can cause spills and leaks, which makes pollution worse. The situation is made worse by a lack of treatment facilities and not following environmental rules. On the other hand, good ways to handle hazardous waste can cut down on pollution in the environment by a lot. Incineration, secure landfilling, stabilisation, and recycling are all scientific ways to treat waste that stop dangerous compounds from getting into the environment.

The level of contamination in the environment is directly affected by how well hazardous waste is handled. To keep hazardous waste from polluting land and water, it is important to improve management methods, enforce rules, and use technologies that are good for the environment.

1.5 Scope of study

- To investigate hazardous waste management strategies in designated industrial regions.
- To look into how hazardous waste affects the condition of the soil
- To look at how hazardous waste affects pollution in surface and groundwater
- To check if the rules for handling hazardous waste are being followed
- To recommend actions for diminishing soil and water contamination

1.6 Objectives of the Study

- To comprehend the idea and classifications of hazardous waste
- To look into how hazardous trash is currently being handled

ISSN (Online): 2455-3662
EPRA International Journal of Multidisciplinary Research (IJMR) - Peer Reviewed Journal
Volume: 12| Issue: 1| January2026|| Journal DOI: 10.36713/epra2013 || SJIF Impact Factor 2025: 8.691 || ISI Value: 1.188

- To examine the correlation between hazardous waste management and soil contamination.
- To examine the effects of hazardous waste on water quality
- To recommend practical methods for better handling of hazardous waste

2. REVIEW OF LITERATURE

1. Rakesh Kumar (2016) looked into how industrial hazardous waste affects pollution in India's biggest industrial areas. His research shown that inadequate disposal of hazardous waste results in soil contamination by heavy metals and harmful compounds. The study showed that putting trash in landfills in a way that isn't scientific and leaking from waste storage facilities really hurts the quality of the soil and makes farming less productive. The study also found that polluted soil is a second source of groundwater pollution.
2. Anil Kumar Gupta (2017) looked at how Indian manufacturing companies handle hazardous waste. He discovered that pollution of soil and water is caused by things like not separating things, bad transportation systems, and not having enough treatment facilities. The investigation made it clear that businesses that don't follow environmental rules produce garbage that hasn't been processed, which pollutes neighbouring land and water bodies. Gupta said that to protect the environment, the government should make sure that rules are followed more strictly.
3. Sunita Narain (2018) critically examined environmental governance and hazardous waste policies in India. She pointed out big holes in the enforcement of hazardous waste management standards and the effects they have on the environment. Her findings showed that poor monitoring systems let dangerous waste permeate soil and groundwater, especially in areas with a lot of factories. The study emphasised the necessity for sustainable waste management and enhanced policy involvement to safeguard natural resources.
4. Vijay Kumar Sharma (2019) examined the correlation between industrial waste disposal methods and groundwater contamination. His research showed that leachate from hazardous waste dumps has a lot of dangerous compounds that get into groundwater sources. The research determined that inadequate hazardous waste management significantly contributes to the deterioration of water quality in India's industrial and semi-urban regions.
5. P. K. Sikdar (2020) examined groundwater contamination in urban and industrial areas of India. His research shown that the disposal of hazardous waste and the discharge of industrial effluents substantially impact groundwater quality. Sikdar stressed that soil is a way for pollutants to get into water systems. The study emphasised the critical necessity for scientific waste disposal and consistent groundwater monitoring.
6. Sanjay Kumar Singh (2021) looked into the dangers to health and the environment that come with handling hazardous waste. His studies found that improper management and disposal of hazardous material were major drivers of pollution in soil and surface water. The research indicated that enhanced waste treatment technologies and employee training can mitigate environmental pollution.
7. Neeraj Kumar (2022) examined the effects of hazardous waste on soil quality and agricultural land adjacent to industrial areas. The research discovered elevated concentrations of heavy metals in soil samples obtained from areas adjacent to hazardous waste disposal sites. The study found that being around hazardous trash for a long time seriously damages soil fertility and makes food unsafe.
8. Rajesh Kumar Mishra (2023)examined contemporary trends in hazardous waste management and environmental degradation in India. His research focused on the connection between bad waste management and the rise in contamination of land and water. The study underscored the necessity of implementing sustainable hazardous waste management procedures, recycling, and stringent adherence to environmental legislation to mitigate pollution levels.

3. RESEARCH METHODOLOGY

3.1 Design for Research

The study employs a descriptive and analytical research design. This concept is appropriate for evaluating current hazardous waste management procedures and assessing their effects on soil and water contamination in designated industrial regions.

3.2 Size of the Sample and Method of Sampling

Study Area: Chosen industrial zones

Size of Sample:

- 50 industrial units
- 40 people working with trash
- 10 people in charge of the environment
- Total number of people who answered: 100

Sampling Technique: We utilised purposive sampling to choose industries and people who work directly with hazardous waste management.

3.3 Ways to Collect Data

Main Data

- Questionnaires that are structured
- Observations in the field
- Unplanned interviews with employees and officials

Data from other sources

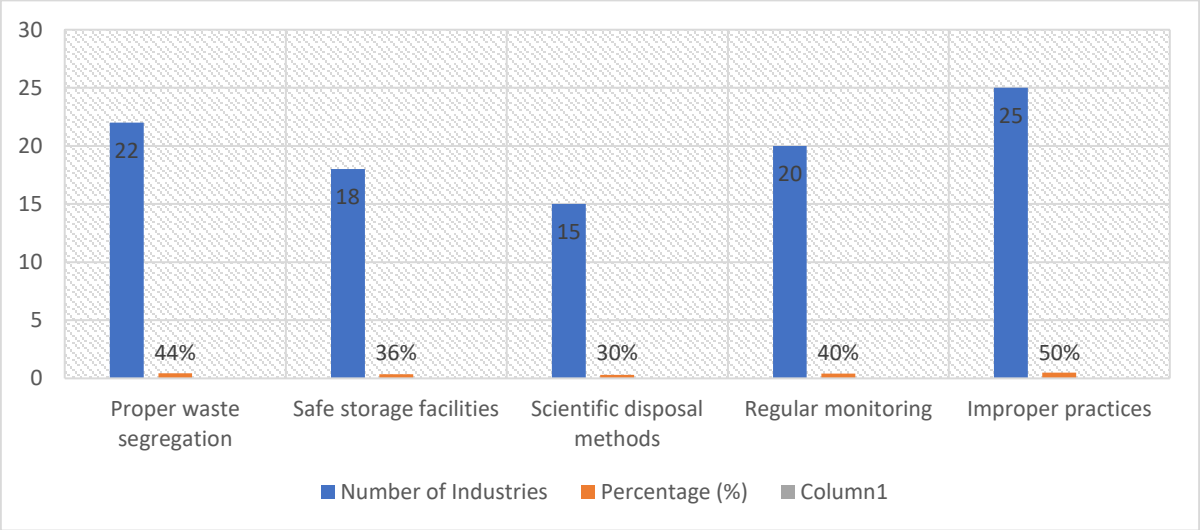
- Reports from the government
- Publications from the Pollution Control Board
- Journals and publications about research

ISSN (Online): 2455-3662
EPRA International Journal of Multidisciplinary Research (IJMR) - Peer Reviewed Journal
Volume: 12| Issue: 1| January2026|| Journal DOI: 10.36713/epra2013 || SJIF Impact Factor 2025: 8.691 || ISI Value: 1.188

4. DATA ANALYSIS

Table 1: Hazardous Waste Management Practices Followed by Industries

Practice Followed	Number of Industries	Percentage (%)
Proper Waste Segregation	22	44%
Safe Storage Facilities	18	36%
Scientific Disposal Methods	15	30%
Regular Monitoring	20	40%
Improper Practices	25	50%

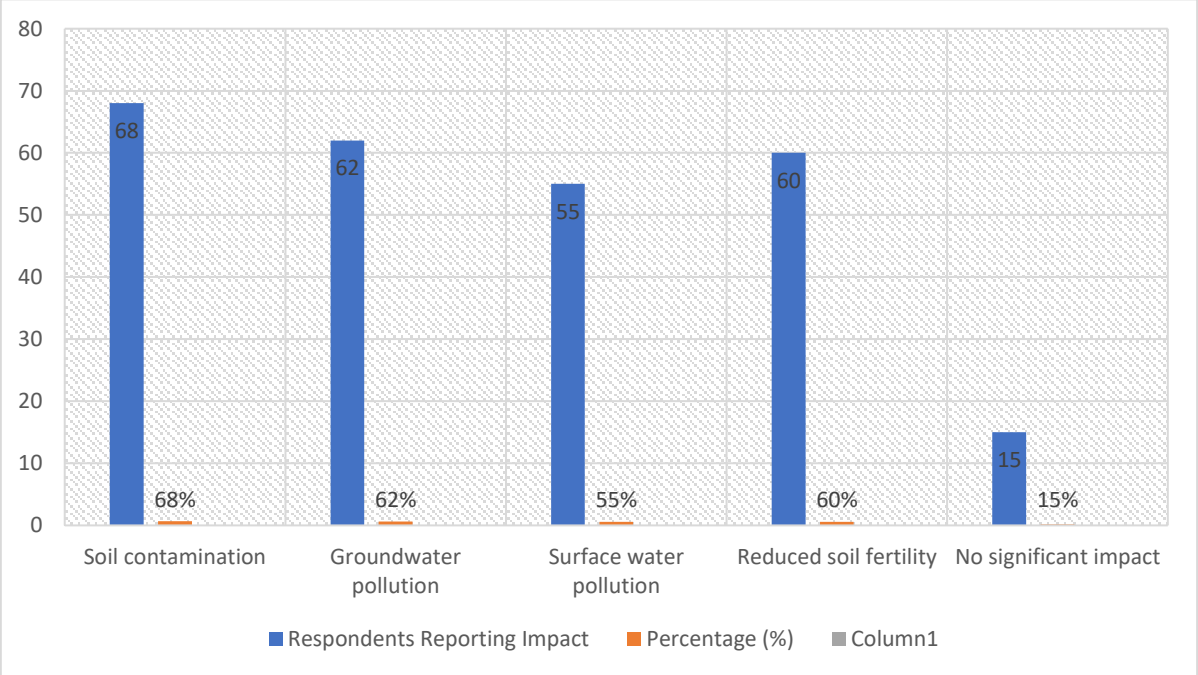


Interpretation

The table shows that only 30–40% of industries follow scientific waste disposal and monitoring practices, while 50% still follow improper hazardous waste management practices. This indicates a high risk of environmental pollution.

Table 2: Impact of Hazardous Waste on Soil and Water Quality

Type of Impact	Respondents Reporting Impact	Percentage (%)
Soil Contamination	68	68%
Groundwater Pollution	62	62%
Surface Water Pollution	55	55%
Reduced Soil Fertility	60	60%
No Significant Impact	15	15%



ISSN (Online): 2455-3662
EPRA International Journal of Multidisciplinary Research (IJMR) - Peer Reviewed Journal
Volume: 12| Issue: 1| January2026|| Journal DOI: 10.36713/epra2013 || SJIF Impact Factor 2025: 8.691 || ISI Value: 1.188

Interpretation
A majority of respondents reported soil and water contamination due to hazardous waste. Soil pollution was reported by 68% respondents, showing it as the most affected environmental component.

5. DISCUSSION

The study's results clearly show that there is a substantial link between how hazardous waste is handled and pollution of soil and water. The results show that a lot of businesses don't follow the right steps for handling hazardous trash, which is bad for the environment. Toxic compounds escape into soil and water systems because of bad waste separation, improper storage, and unscientific disposal methods.

The percentage study shows that soil contamination is worse than water pollution because toxins go straight into the soil from dumping sites and storage facilities. These pollutants move into groundwater over time, which makes the water quality worse. People also said that the soil fertility had gone down, which makes it harder for farms to grow crops near industrial regions.

Industries that used scientific methods for waste management reported decreased levels of contamination, which shows that proper hazardous waste treatment works. However, the absence of stringent enforcement of rules and poor monitoring mechanisms are still big problems. The conversation makes it clear that bad hazardous waste management is a serious environmental problem that has to be dealt with right away by politicians and people in the sector.

6. CONCLUSION

The study finds that how hazardous waste is handled has a big impact on how polluted the soil and water are in industrial locations. Soil and groundwater pollution are greatly increased by not properly processing, storing, and getting rid of hazardous material. The results show that many industries don't follow environmental rules, which hurts the environment.

Soil is the first place where hazardous waste pollution happens, and polluted soil can also spread water pollution. Heavy metals and other hazardous compounds not only make the environment worse, but they also represent major threats to human health and the long-term viability of farming. The study stresses that good ways to handle hazardous waste, such separating it properly, throwing it away in a scientific way, and keeping an eye on it often, can greatly lower pollution levels.

The research shows that we need to quickly make hazardous waste management systems stronger, make sure that rules are followed more, and encourage businesses to use more environmentally friendly methods to protect soil and water resources.

7. SUGGESTIONS

- Strictly following the guidelines for handling hazardous trash
- Regular checks on the quality of soil and water in industrial areas
- Using scientific approaches to treat and get rid of garbage
- Training programmes for people who deal with dangerous garbage
- Encouraging recycling and reducing waste
- Industries are more mindful of how to protect the environment.
